CHAPTER

ONE

ABOUT PROJECT

This project is funded by both the Defense Research and Development Canada (DRDC) and the National Research Council (NRC). These organizations are working alongside Carleton University students to develop a pip installable library that contains all the parsers used to convert radar and lidar data to readable csv files. The radars used in this project are the Novelda X4M03, X4M300, X4M200 and the TI-AWR1642. The lidar used is the Ouster OS1-16.

Contents:

1.1 Radar Information

1.1.1 About X4 radar

The X4 radars are IR-UWB and can work at frequencies ranging from 6 GHz to 10.2 GHz. The total number of bins that can be sampled is 1536.

X4M300 Specs

• Detection Time: 1.5 - 3.0 seconds

• Range: 9.4 meters

• Antenna: Tx for transmission and Rx for receiving

• Baseband data output: 17 baseband/ssecond

• System on chip: Novelda UWB X4

X4M200 Specs

• Detection Time: 3.0 - 5.0 seconds

• Range: 5 meters

• Antenna: Tx for transmission and Rx for receiving

• Baseband data output: 17 baseband/ssecond

• System on chip: Novelda UWB X4

1.1.2 Configuring X4 radar

- 1. Begin by initializing to default values using prebuilt function x4driver_init()
- 2. Set PRF using function x4driver_set_prf_div(...)

Note: The common PLL value of 243 MHz is divided by the arguemnent passed in to x4driver_set_prf_div(...) to get a PRF value

Note: Make sure that when changing the PRF that frame length is shorter than 1/PRF and avoid sampling previous pulse when transmitting next pulse.

- 3. Set DAC sweep range minimum and maximum using x4driver_set_dac_min() and x4driver_set_dac_max()
- 4. Set 0 reference using x4driver_set_frame_area_offset()
- 5. Set frame area using function x4driver_set_frame_area() that takes two arguements, one for start of frame and one for end of frame.

1.1.3 Setting radar FPS

To set the radar FPS the following parameters are required, PRF, iterations, pulse per step, dac max and dac min range as well as duty cycle.

$$FPS = \frac{PRF}{iteration*pulse_per_step*(dac_max - dac_min + 1)}*dutycycle$$

Our Novelda radar is configured to a FPS of 17 pulse/second so if you wanted to change FPS then the above parameter would need to be changed.

Note: The resulting FPS can be read using the built-in function *x4driver_get_fps()*.

Example pulse per step calculation

• PRF: 16 MHz

• X4_duty_cycle: 95%

• dac max: 1100

• dac min: 949

• iteration: 64

• FPS: 17

$$pulse_per_step = \frac{PRF}{iteration*FPS*(dac_max - dac_min + 1}*D$$

$$pulse_per_step = \frac{16MHz}{64*17*150}*0.95$$

$$pulse_per_step = 87$$

1.2 Linux setup

To install Linux with Ubuntu v18.04 on a Windows PC, users must install the following files:

VirutalBox Software

Ubuntu 18.04 download

1.2.1 Quick tips for linux beginners

- Set the network setting to use bridged adapter so Linux doesn't share the same ip address as your Windows PC.
- Insert guest addition CD image found in the *Devices* tab for auto-adjusted screen resolutions.
- Use ~/ to cd to home directory

1.3 X4 Radar

1.3.1 Parser for iq data

Pass your .dat file from the recording into this function to generate a readable csv file with complex values as data. .. automodule:: X4_parser

members iq_data

1.3.2 Parser for raw data

Pass your .dat file from the recording into this function to generate a readable csv file with raw values as data. .. automodule:: X4_parser

noindex

members raw_data

1.3.3 X4 Record and playback code

Target module: X4M200,X4M300,X4M03

Introduction:

XeThru modules support both RF and baseband data output. This is an example of radar raw data manipulation. Developer can use Module Connecter API to read, record radar raw data, and also playback recorded data.

Command to run: python X4_record_playback.py -d com3-b -r

- -d com3 represents device name and can be found when starting Xethru Xplorer.
- -b to use baseband to record, default is radio frequency.
- -r to start recording.

X4_record_playback.clear_buffer(mc)

Clears the frame buffer

Parameter:

mc: object module connector object

1.2. Linux setup 7

X4_record_playback.main()

```
Creates a parser with subcatergories.
     Return:
     A simple XEP plot of live feed from X4 radar.
X4 record playback.on file available (data type, filename)
     Returns the file name that is available after recording.
     Parameter:
     data_type: str data type of the recording file.
     filename: str file name of recording file.
X4_record_playback.on_meta_file_available (session_id, meta_filename)
     Returns the meta file name that is available after recording.
     Parameters:
     session_id: str unique id to identify meta file
     filename: str file name of meta file.
X4_record_playback.playback_recording (meta_filename, baseband=False)
     Plays back the recording.
     Parameters:
     meta filename: str Name of meta file.
     baseband: boolean Check if recording with baseband iq data.
X4_record_playback.reset (device_name)
     Resets the device profile and restarts the device
     Parameter:
     device_name: str Identifies the device being used for recording using it's port number.
X4_record_playback.simple_xep_plot(device_name, record=False, baseband=False)
     Plots the recorded data.
     Parameters:
     device_name: str port that device is connected to.
     record: boolean check if device is recording.
     baseband: boolean check if recording with baseband iq data.
     Simple plot of range bin by amplitude.
```

1.4 TI parser code

```
TI_parser.readTIdata(filename, csvname)
```

Takes a .bin binary file and outputs the iq data to a csv file specified by csvname.

Parameter

filename: str file name of binary file.

csvname: str csv file name that stores the iq data from binary file.

Example

```
>>> readTldata('Tldata.bin','Tldata')
>>> 'converted'
```

Returns

Readable csv file containing complex data.

1.5 Ouster OS1 Lidar

1.5.1 Specs

All below specs are for OS1-16 lidar that was used in this project - Works on channel 16, 64, 128. - Maximum range of 120 meters. - Field of view of 33.2 degree vertically and 360 degree horizontally. - Sampling rate of 327,680 points/second.

1.5.2 Setup lidar

- 1. Connect lidar interface box to router that supports Gigabit connection.
- 2. Connect lidar to lidar interface box via cable.
- 3. Determine the ip address your router gave the lidar when it connected to the network and jot it down.
- 4. Determine your linux ip adress by running ifconfig in terminal and jot it down.

1.5.3 Ouster Github

The following Github page provides information on how to view raw data stream, visualize data and use a robot operating system (ROS) to save recorded data in a .bag file. ROS commands can also replaying data in .bag files and convert .bag files to .csv files.

Note: Some version of Linux running Ubuntu must be used. It is recommended to run Ubuntu 18.04 for best results. Follow instructions in *Ubuntu* page for more details on installing Linux with Ubuntu.

Ouster client

The Ouster client allows users to see the raw data stream that the lidar is collecting and sending to the specified ip address. Instruction on building the client in Linux can be found here Building client.

Running client

- 1. cd/path/to/ouster_client_example
- 2. type ./ouster_client_example <os1_hostname> <udp_dest_ip>

1.5. Ouster OS1 Lidar 9

<os1_hostname> is hostname/ip address of lidar.

<udp_data_dest_ip> is the destination ip address the lidar sends data to. e.g. ip address from running ifconfig.

Ouster visualization

The Ouster visualization is used for building a basic visualizer frame of collected lidar data. Instructions on building visualizer and it's dependencies can be found here Building visualizer. The visualizer can be run in real time and with recorded data.

Running visualizer

- 1. cd/path/to/ouster_viz/build
- 2. ./viz -m <frame_size> <os1_hostname> <udp_data_dest_ip>

<frame_size> is the size of the visualization frame and can ONLY be the following: 512x10, 512x20, 1024x10, 1024x20, 2048x10.

<os1_hostname> is the ip address of lidar.

<udp_data_ip_dest> is the ip address lidar sends data to.

Ouster ROS

Note: For Ubuntu 18.04 users it is best to use **ROS Melodic** as **ROS Kinetic** (The ROS provided on the GitHub page) is only compatible with Ubuntu 16.04 and lower.

Building the ROS Node can be found here Building ROS Kinetic.

For Ubuntu 16.04 users and lower: Installation of ROS Kinetic

For Ubuntu 18.04 users: Installation of ROS Melodic

For new users to using ROS: ROS Tutorials

Running ROS Node

Note: Before typing any commands make sure to always source the setup.bash file in your created ROS workspace otherwise it will return a error. The file can be sourced with the command *source /path/to/myworkspace/devel/setup.bash*.

For recording lidar data:

1. roslaunch ouster_ros os1.launch os1_hostname:=<os1_hostname> os1_udp_dest:=<os1_udp_dest> li-dar_mode<:=lidar_mode>. The option to visualize live data can be turned on by adding viz:=true to the roslaunch command.

<os1_hostname> is the ip address of the lidar

<os1_udp_dest> is the ip address the lidar sends data to

dar_mode> is the size of the lidar visualization frame

2. rosbag record -O <recorded__bag_filename> /os1_node/imu_packets /os1_node/lidar_packets in a new terminal

/os1_node/imu_packets and /os1_node/lidar_packets are your topic names that the lidar sends messages to via the node you built. These topic names can be changed to user preference.

Note: DO NOT close the terminal with the roslaunch command open otherwise rosbag will crash.

For replaying lidar data:

- 1. roslaunch ouster_ros os1.launch replay:=true os1_hostname:=<os1_hostname>
- 2. In a **new** terminal run rosbag play

 tag_filename>

Note: DO NOT close the terminal with the roslaunch command open otherwise rosbag will crash.

Converting data to csv file: Run rostopic echo "topic name" -b "bag_filename" -p > filename.csv

Note: To find topic names run the command *rosbag info <bag_filename>*

1.6 Test file

```
class test.TestParser(methodName='runTest')
```

test_TI()

Method to test if .bin binary file was converted successfully to .csv file with iq data put together.

Returns

Tells user if binary file was correctly converted to csv file.

test_iq()

Method to test if .dat binary file was converted successfully to .csv file with in-phase and quadrature components together.

Returns

Tells user if binary file was correctly converted to csv file.

test_raw()

Method to test if .dat binary file was converted successfully to .csv file with in-phase and quadrature component separated.

Returns

Tells user if binary file was correctly converted to csv file.

```
Convert X4 binary .dat file to csv
X4 data collection code
Convert TI binary .bin file to csv
Unit tests for radar parser
```
